

CSC 4480 – Advanced SQL Lab

Write SQL statements for the following. Save a copy of your SQL and the results for each item, for your reference when we go over the solutions.

1. Find out how many department managers there are in the company.
2. List the last name, first name and salary for department managers in the company. Sort the results by the highest salary first, then by last name for equal salaries.
3. Find the average salary for all department managers in the company. Name the result "avg_mgr_salary".
4. For each department whose average salary of all employees in the department is greater than twice the minimum salary in the company, retrieve the department name and average salary.
5. Create a view called "Dept_Payroll" that lists the dept. number, dept. name, total staff count and total payroll for each department, for all departments with more than 2 employees. Use the column names "total_staff" and "total_payroll" in your view.
6. Display the Dept_Payroll view ordered by highest to lowest total_payroll.
7. Retrieve the department name with the highest payroll from the Dept_Payroll view.
8. For all employees who are assigned to projects, list their last name and total hours worked.
9. List all employees and their total hours worked across all projects, even if the employee isn't assigned to any projects. Sort the results by last name ascending.
10. For all employees, list the project number, project name and hours worked for the projects on which the employee is working.
11. Select the names and number of projects the employee is working on, for all employees working on more than one project. Order your results so that the employee who is working on the most projects is at the top of the list.
12. Select the name and SSN of all employees who have no dependents.
13. Change the Book table to include the ISBN of the book. The ISBN is 13 digits long.
